What is Design Verification?

What is Design Verification?

“~~Design~~ Verification is the process used to gain confidence in the correctness of a design w.r.t. the requirements and specification.”

Types of verification:

- Functional verification
- Timing verification
- ...
- What about performance?

Annex A (informative)

The Role of Testing in Verification and Validation

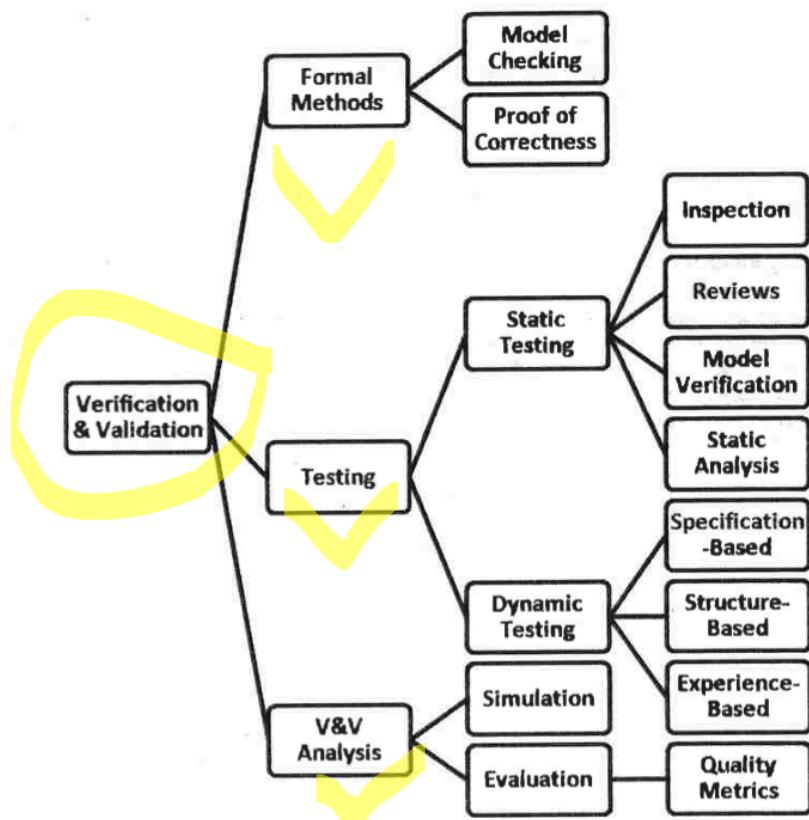

Figure 11 — Hierarchy of Verification and Validation activities

Figure 11 defines the complete nature of verification and validation (V&V) activities. V&V can be done on system, hardware, and software products. These activities and planning are defined and refined in IEEE 1012 and ISO/IEC 12207. Much of V&V is accomplished by testing. The ISO/IEC 29119 standard addresses the Dynamic and Static software testing (directly or via reference), thus covering parts of this verification and validation model. ISO/IEC 29119 is not intended to address all the elements of the V&V model, but it is important for a tester to understand where they fit within this model.

Verification vs Validation

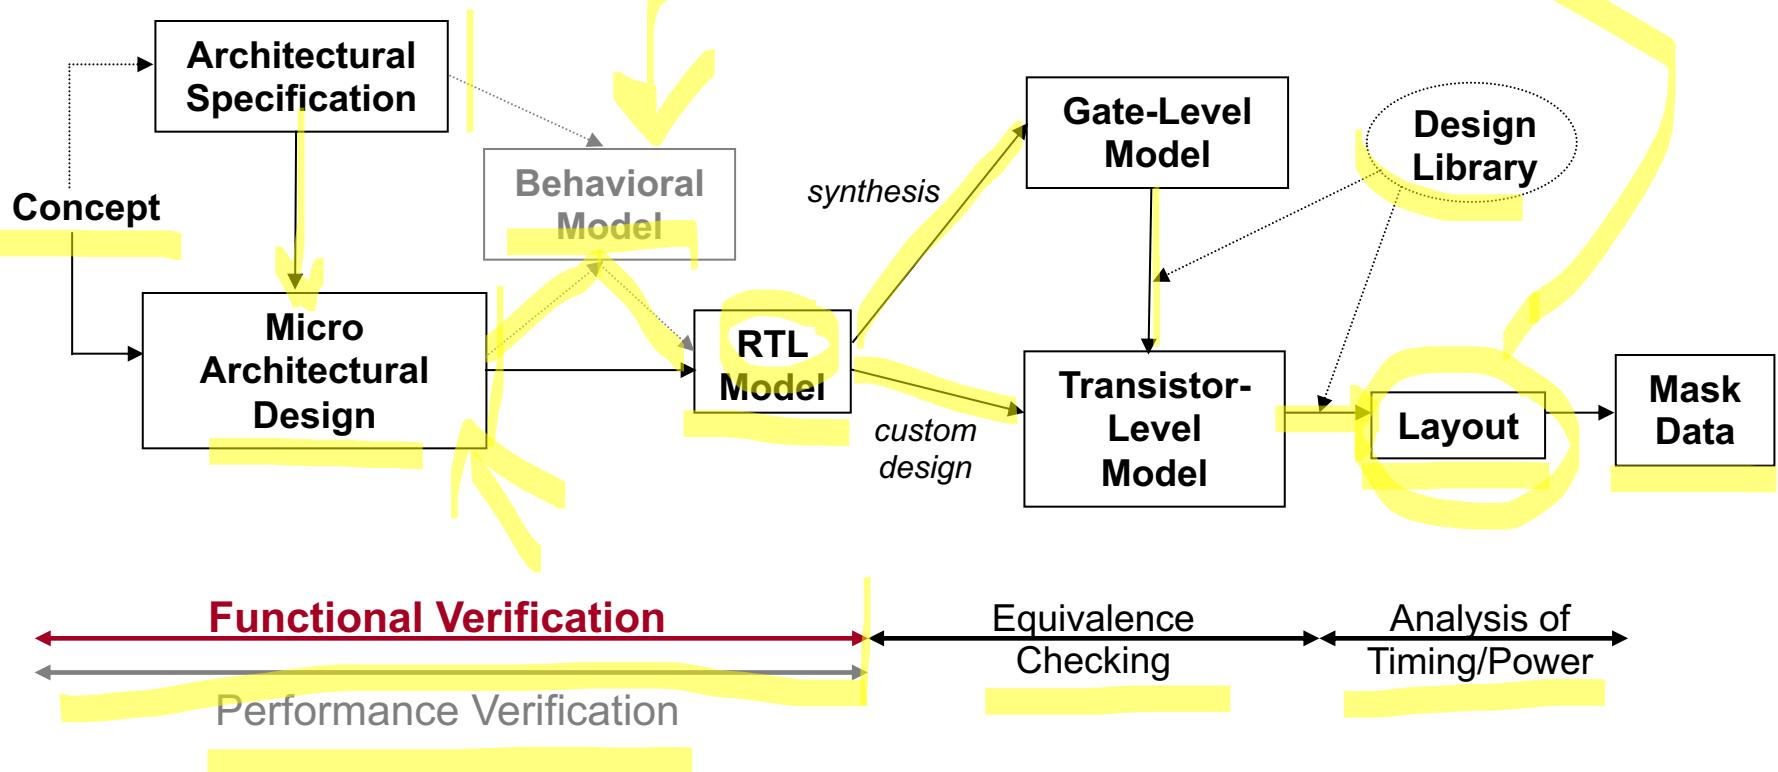

- **Verification:**
 - Confirms that a system has a given input / output behaviour, sometimes called the **transfer function** of a system.
- **Validation:**
 - Confirms that the system's transfer function results in the intended system behaviour when the system is employed in its target environment, e.g. as a component of an embedded system.
- **Validation is sometimes used when verification is meant**

Verification in the IC Design Process

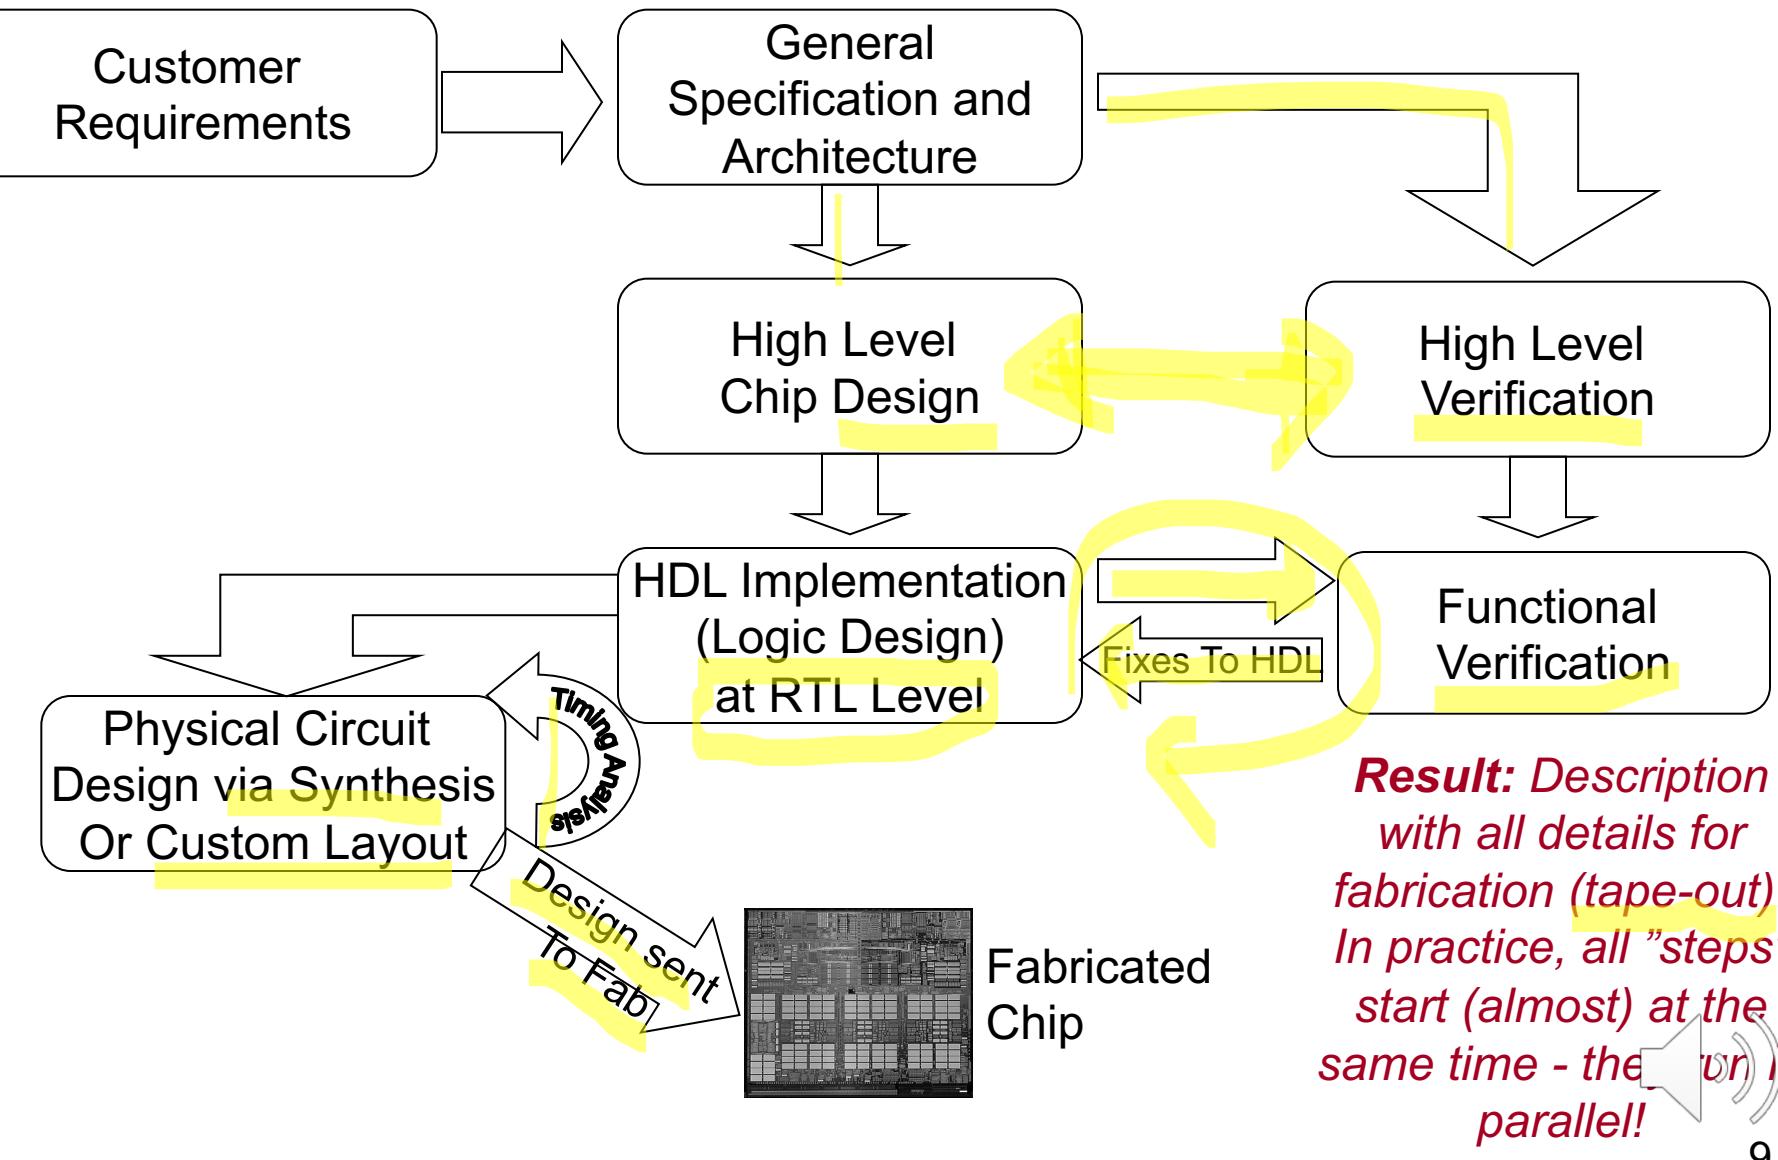

The IC Design Process

Functional verification aims to demonstrate that the functional intent of a design is preserved in its implementation.

Chip Design Process

Why is Verification important?

- Verification is the single biggest lever to effect the triple constraints:

Quality

- A high quality track record preserves revenue and reputation.
- Ideally a team can establish a “right-first-time” track record.

Cost

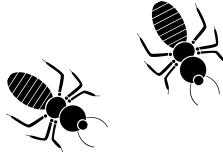

- Fewer revisions through the development/fabrication process means lower costs.
- Respinning a chip costs hundreds of thousands of £/\$/€
+ the associated “lost opportunity” costs.

Timing/Schedule

- Fewer revisions through the development/fabrication process means faster time-to-market.
- Respinning a chip costs 6-8 weeks at least
+ the associated “lost opportunity” costs.

All about Bugs

Types of bugs

How are bugs introduced?

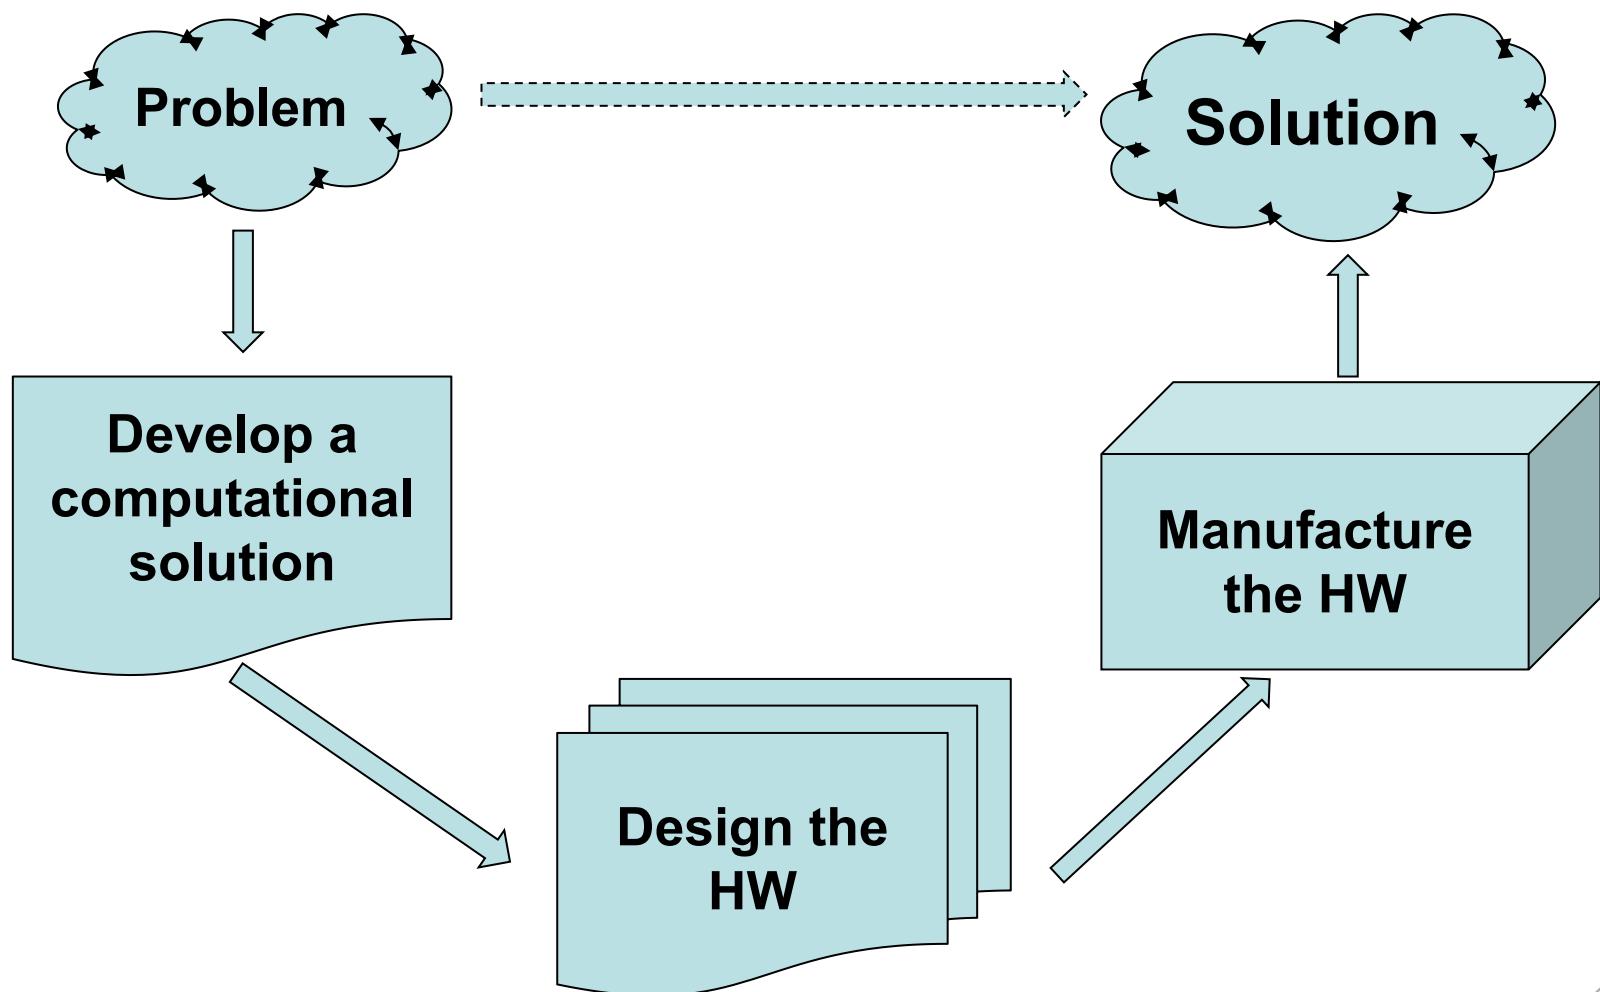

How can bugs be found?

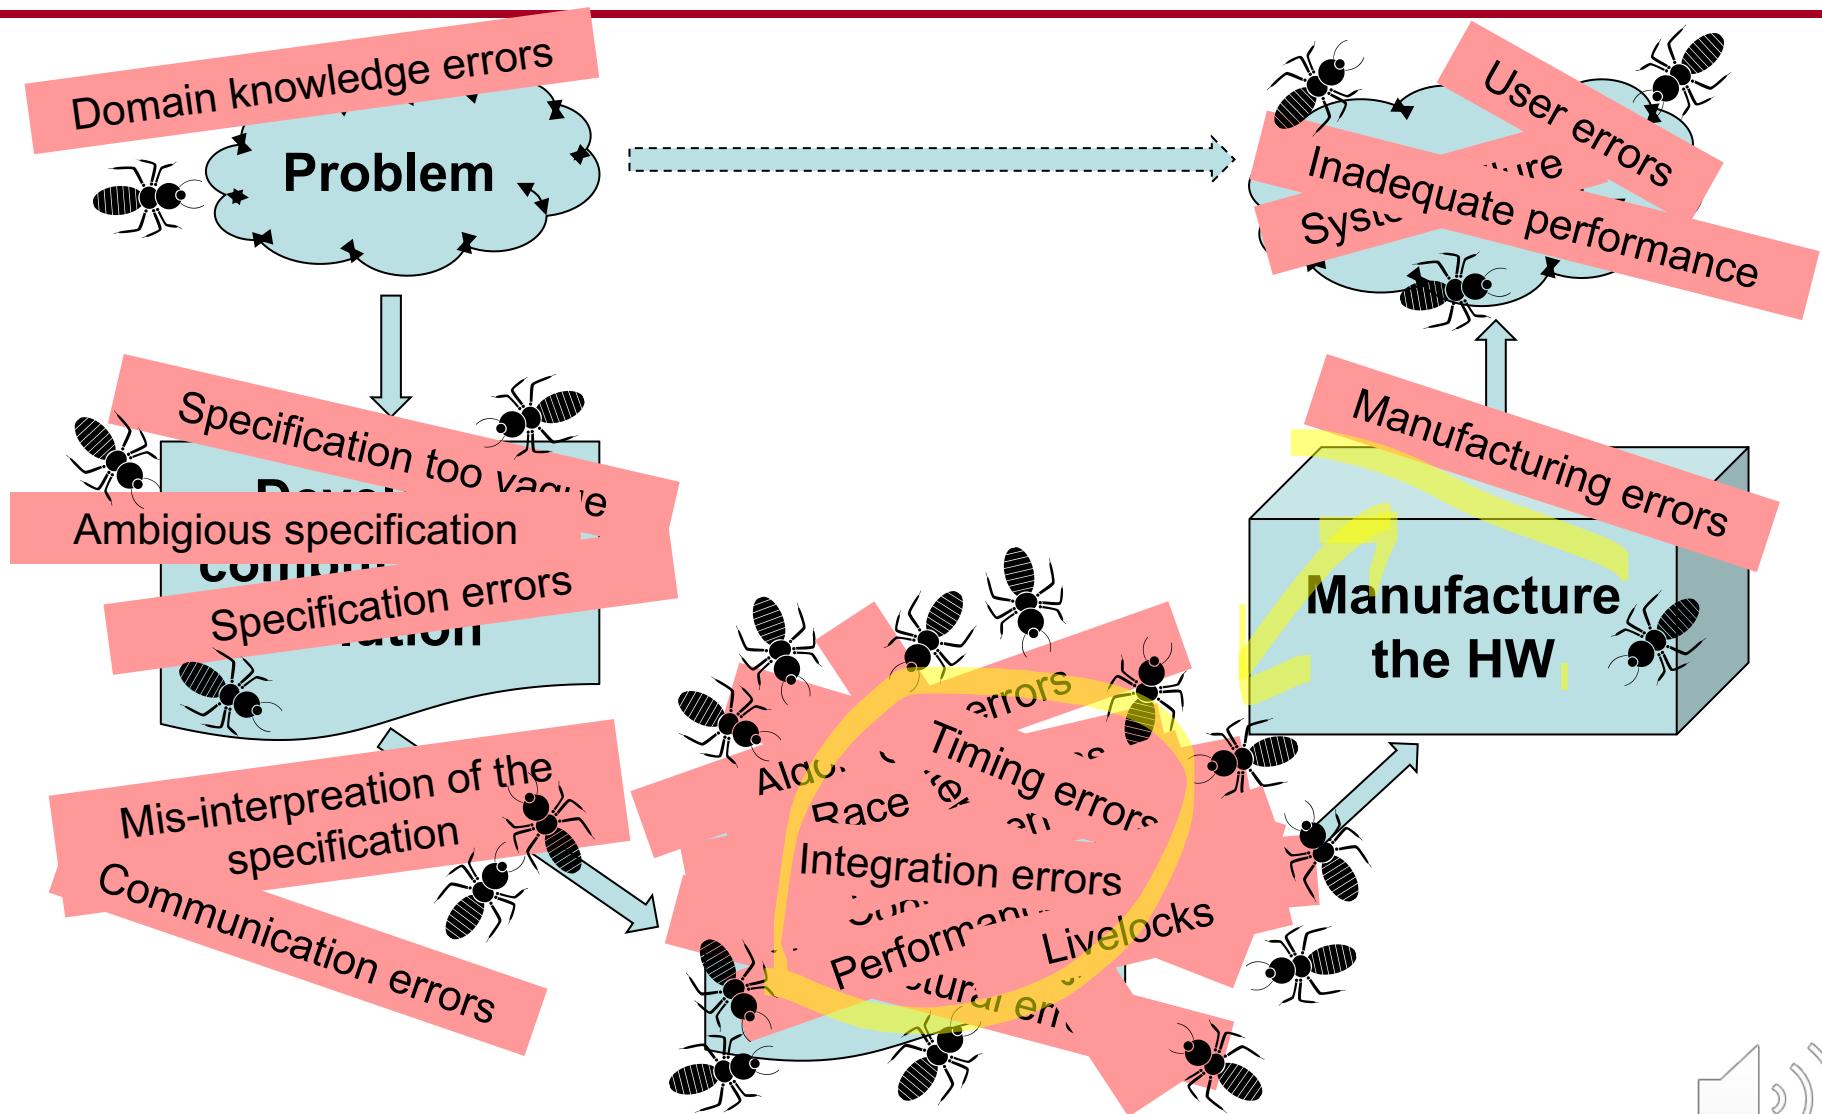

Why do Designs have Bugs?

Why do Designs have Bugs?

Mask costs

(Electronics Weekly, 10 October 2007)

EDA AND IP

Why design a custom integrated circuit?

Mask costs versus line width

Process (μm)	Vdd	Metal	Gates/sq mm	Mask set cost (\$)
0.065	1.0	9	400k	3,000,000
0.09	1.0	9	200k	1,500,000
0.13	1.2	7	100k	750,000
0.18	1.8	5	40k	250,000
0.25	2.5	5	24k	150,000
0.35	3.3	3	12k	40,000
0.5	3.3	3	5k	20,000
0.6	5.0	2	4k	18,000

→ Furthermore, there are other energy-saving techniques you can use that are unique to custom ICs.

For some applications, small size and weight are crucial. Just open up an MP3 player, mobile phone, digital camera or laptop computer for examples of tight and light design. When a set of standard parts is too large or heavy, a custom chip is required.

A designer with access to the full flexibility of a custom chip can create numerous special functions that are difficult to find elsewhere.

For example, special purpose arithmetic units, multi-port memories, and a variety of non-volatile storage circuits can be developed. One can even create magnetic sensors and light sensors ranging from a single sensor to line sensors and two-dimensional video camera chips.

Some companies use custom ICs to better protect their intellectual property. A custom integrated circuit is much more difficult to reverse engineer than a board level design.

The benefits: reliability

Higher integration levels bring greater system reliability.

If your board, with dozens of parts and hundreds of solder connections, can be replaced by one or a few parts with fewer board-level interconnects then the system becomes more reliable. Likewise, higher integration leads to lower manufacturing costs. If the custom IC uses less power, you may be able to use a cheaper power supply. Fewer boards also mean fewer connectors and smaller, less-expensive cabinets.

One company built a product that had two discrete transistors, a pho-

tocell, and a few resistors and capacitors. The circuit board was larger than they needed, they had a measurable field failure rate, and it cost about \$1,000.

The company designed a custom IC with several thousand transistors to implement the same function. It had no measurable field failure rate, and the unit cost was about \$0.50. For the millions of units sold, the payback on this custom chip investment was rapid.

The downside: cost

Custom chips have higher tooling

costs, so if it is important to minimise the cost of prototypes by using standard parts. You may be able to gather a few PCBs and a handful of parts, hand-solder them together, and demonstrate a prototype for about \$2,000. The tooling costs of a custom IC start at about \$18,000 for a set of masks for a 0.6 μm process and go up to about \$3m for a 65nm process.

Products that have high volumes and require huge amounts of processing and memory will need the finest line width processes to get the lowest cost in production. However, for most other products, the manufacturing volumes never make sense for the \$3m tooling cost. Fortunately, the tooling for coarser line widths is much more affordable, yet still larger than that of a PCB.

The downside: time

Custom chips also have longer turnaround times.

If you have a good relationship with your board supplier, a board can be manufactured in a couple of days. Add some shipping and assembly time, and you will still get a new prototype built using standard parts in less than a week.

If you go custom IC, it will be weeks, if not months, before the first chips arrive at your door. And although expediting is often available, the fees are steep and shave only a few days off a lengthy →p30 process.

If you go custom IC, it will be weeks, if not months, before the first chips arrive at your door. And although expediting is often available, the fees are steep and shave only a few days off a lengthy process

A CLASS ACT IS TOUGH TO FOLLOW

New from Schurter's metal line range; the MSM top grade stainless steel switch looks good, performs even better under pressure

- Switching up to 3A 250V AC
- Various sizes - mounting diameter 16, 19, 22 and 30mm
- Highly robust IP67 seal protection
- Resistant to shock IK07 rating
- Low profile to panel and smooth travel
- Various colour options for point or ring illumination - red, green, yellow or blue

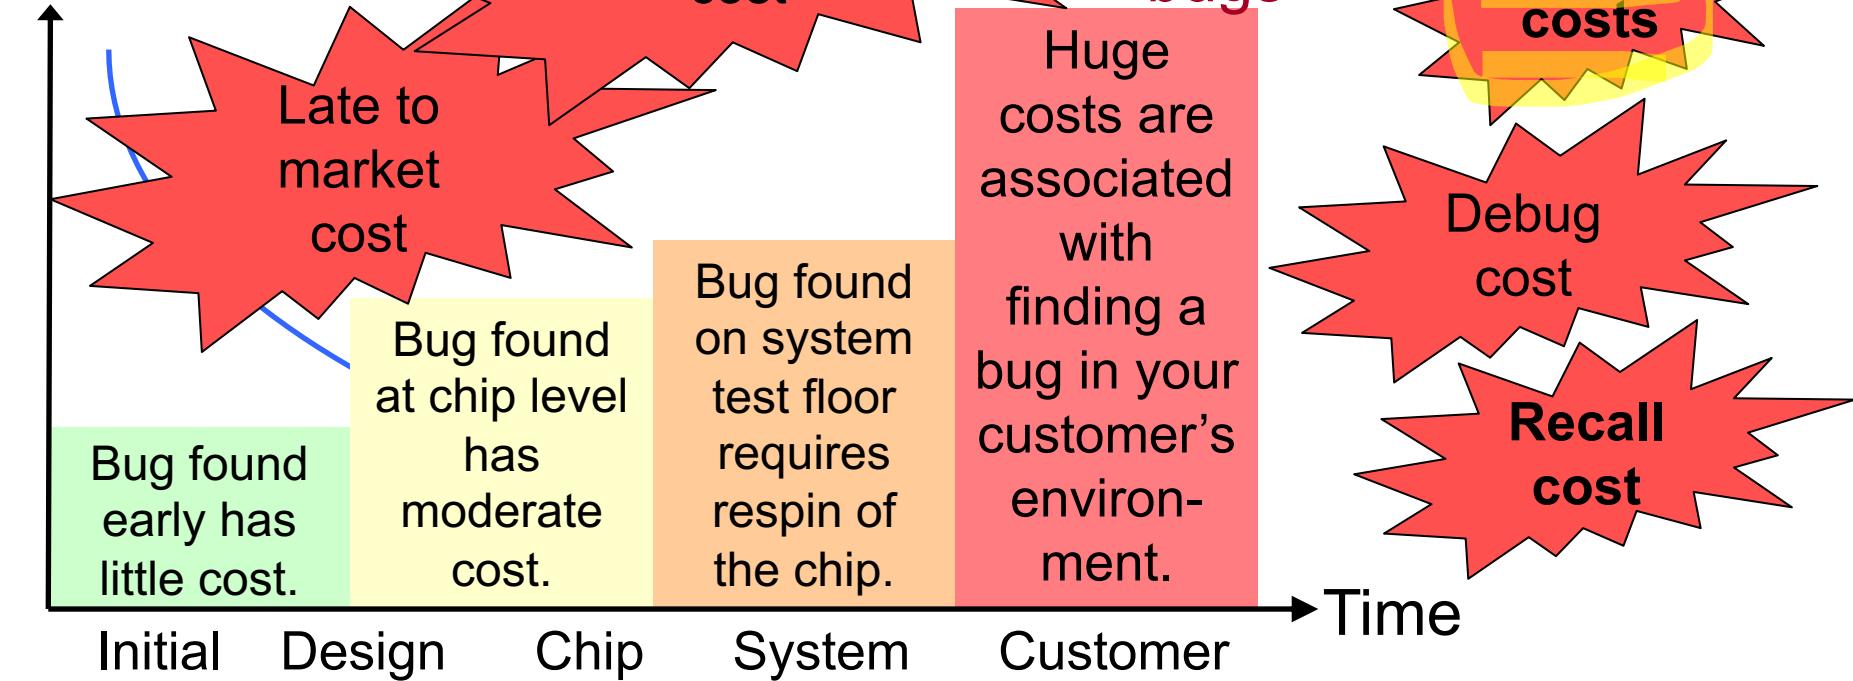

View Schurter's huge range of switches at www.schurter.com or call 01243 810810

Increasing Design Complexity: Moor's Law

ITRS Edition 2009, Design Chapter (<http://www.itrs.net/> and <http://www.itrs2.net/>)
– Hardware and Software Design Gaps versus Time

Getting it right (first time) is more and more difficult:

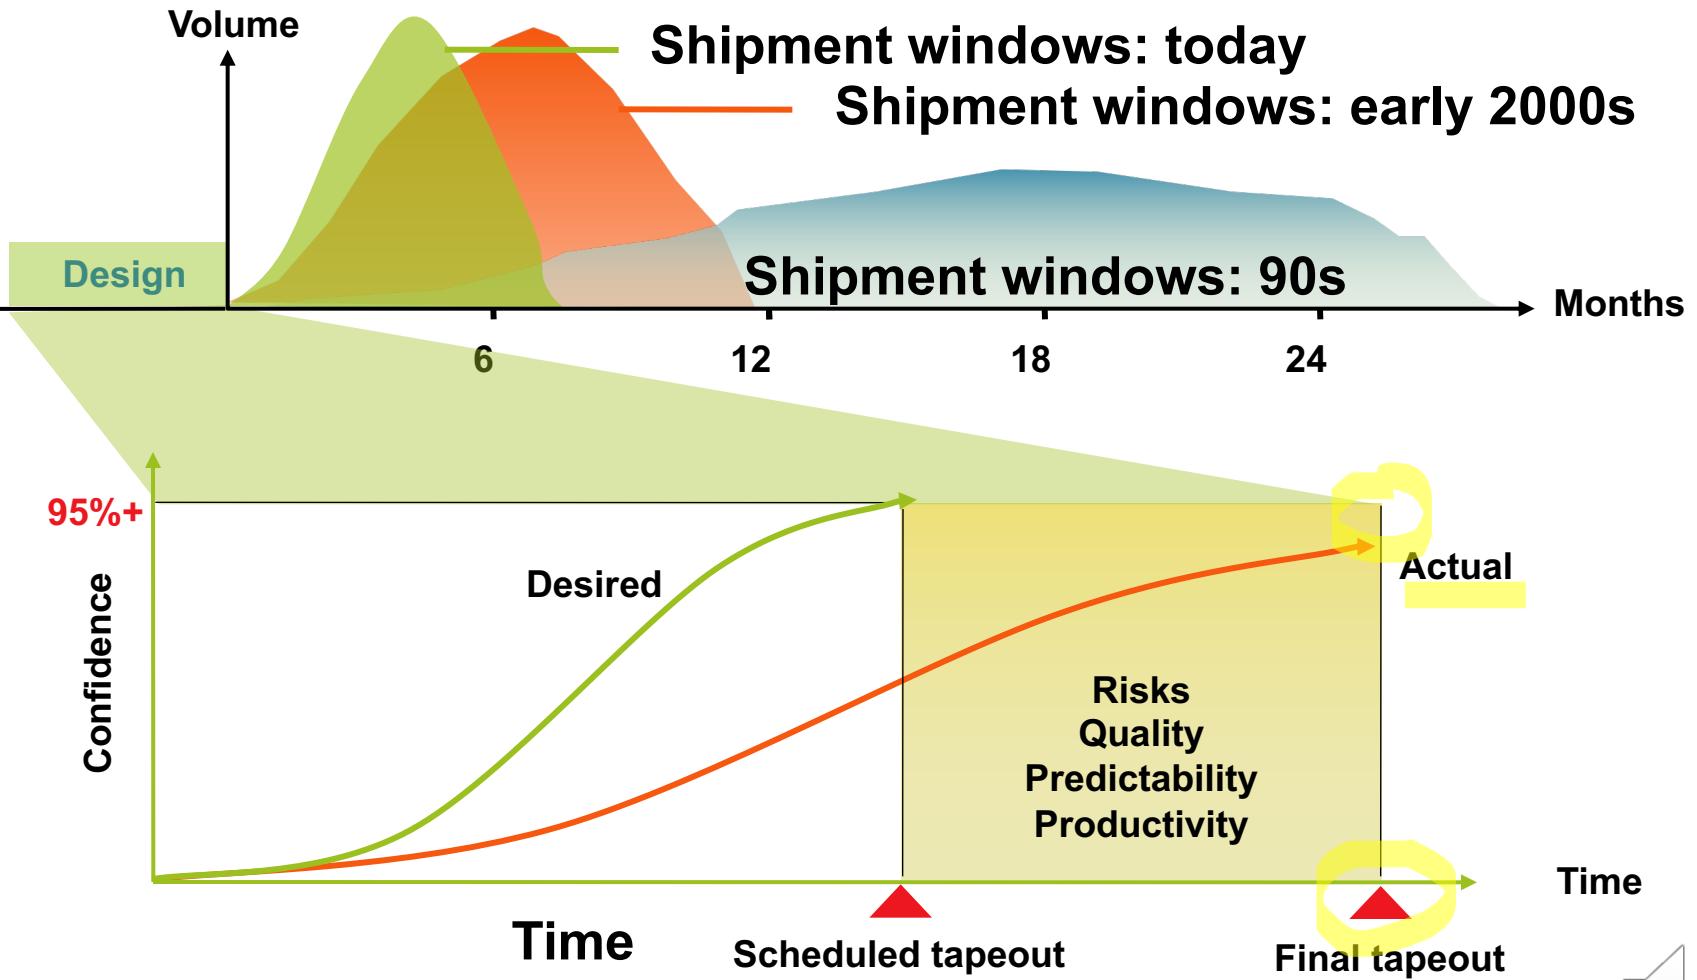

- rapidly increasing design complexity
- tight “time-to-market” constraints

Shorter Time-To-Market Windows

Shorter Time-To-Market Windows

Role of Verification in IC Design

IC design process is complex:

- **Engineers need to balance conflict of interest:**
 - Tight time-to-market constraints vs. increasing design complexity
- **Aim:** “Right-first-time” design, “correct-by-construction”
- More and more time-consuming to obtain acceptable level of confidence in correctness of design!
- **design time << verification time**
 - Remember: Verification does not create value!
 - But it preserves revenue and reputation!
 - Up to 70% of design effort can go into verification.
 - 80% of all written code is often in the verification environment.
 - Properly staffed design teams have dedicated verification engineers.
 - In some cases verification engineers outnumber designers 2:1.

Increasing Verification Productivity

Need to minimise verification time e.g. by using:

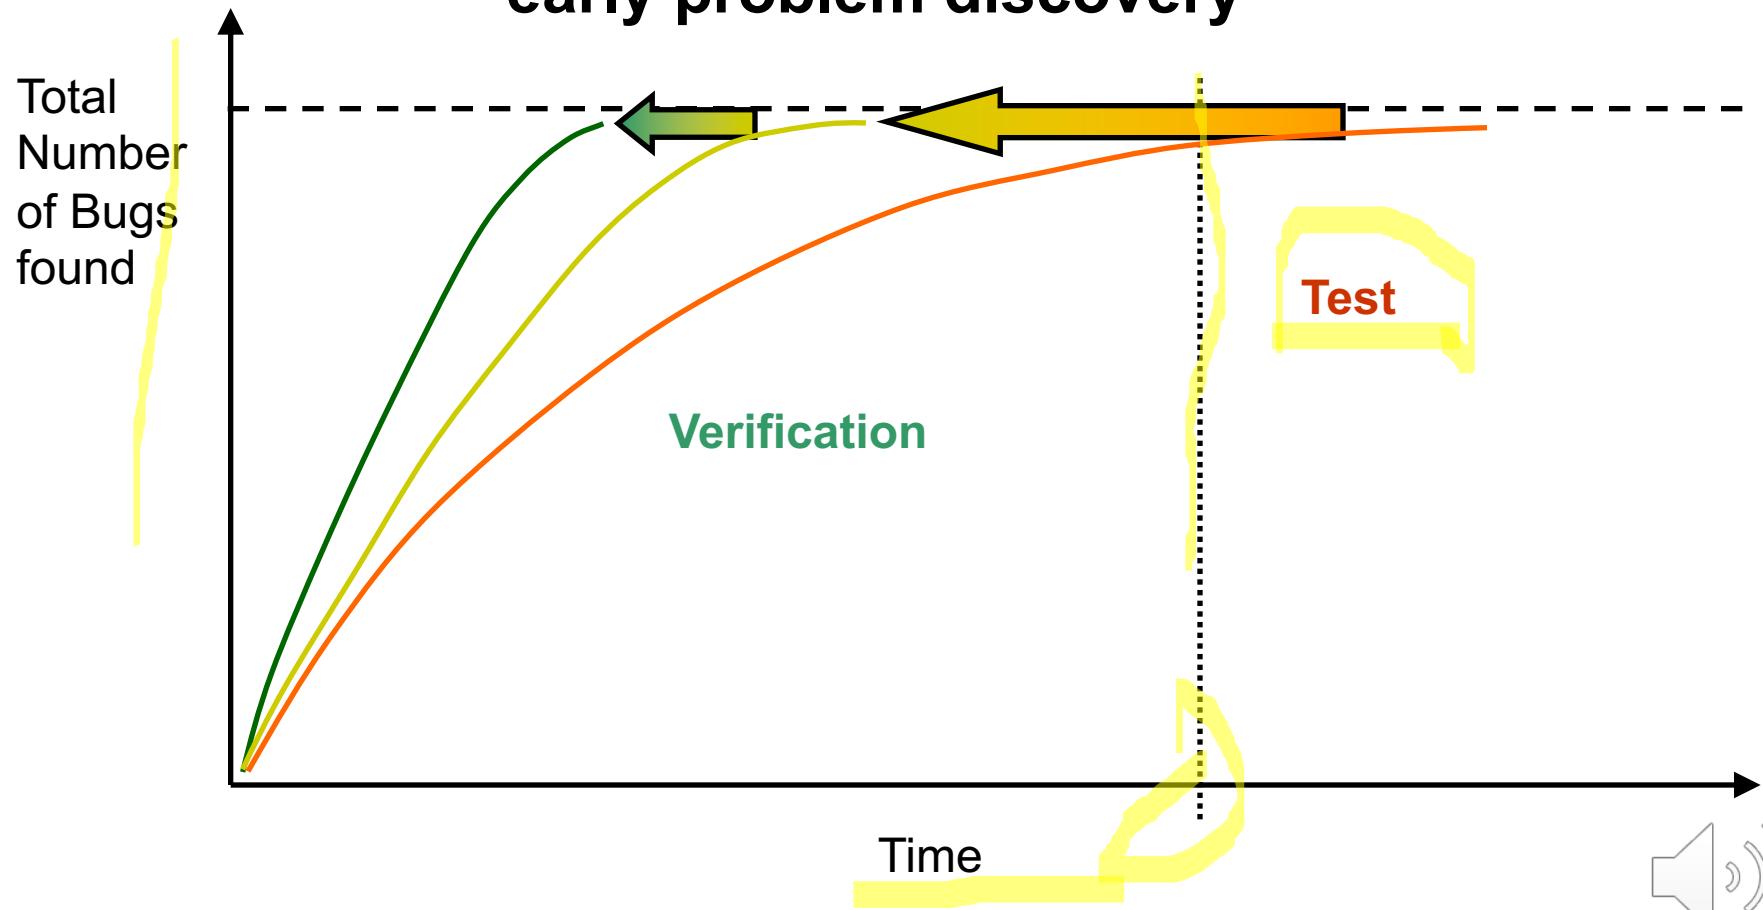

- **Parallelism:** Add more resources
- **Abstraction:**
 - Higher level of abstraction (i.e. C vs Assembly)
 - This often means a reduction of control!
- **Automation:**
 - Tools to automate standard processes
 - Requires standard processes/methodology.
 - Usually a variety of functions, interfaces, protocols, and transformations must be verified.
 - Not all (verification) processes can be automated.

Productivity improvements drive early problem discovery!

Increasing Verification Productivity

What are you
going to verify?

Chip Design Process

How do Designers know whether a circuit is correct?

There is skill, science and methodology behind verification.

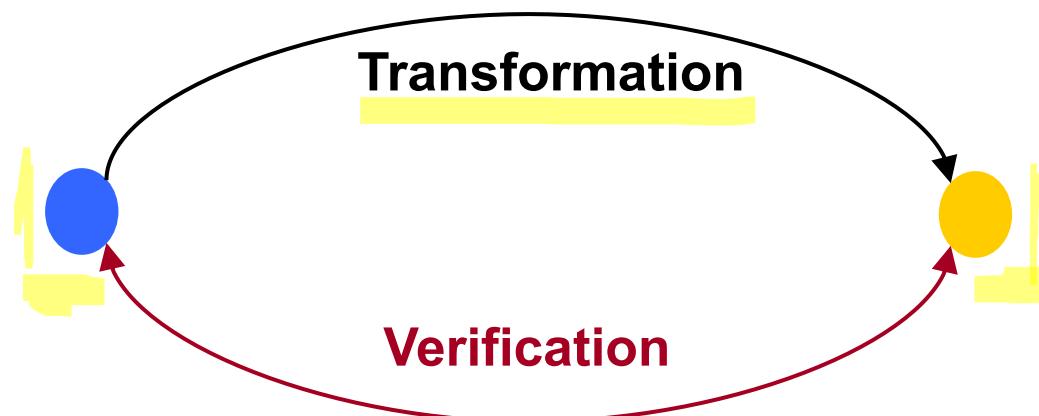

Reconvergence Models

[Bergeron]

Conceptual representation of the verification process

- Most important question:

What are you verifying?

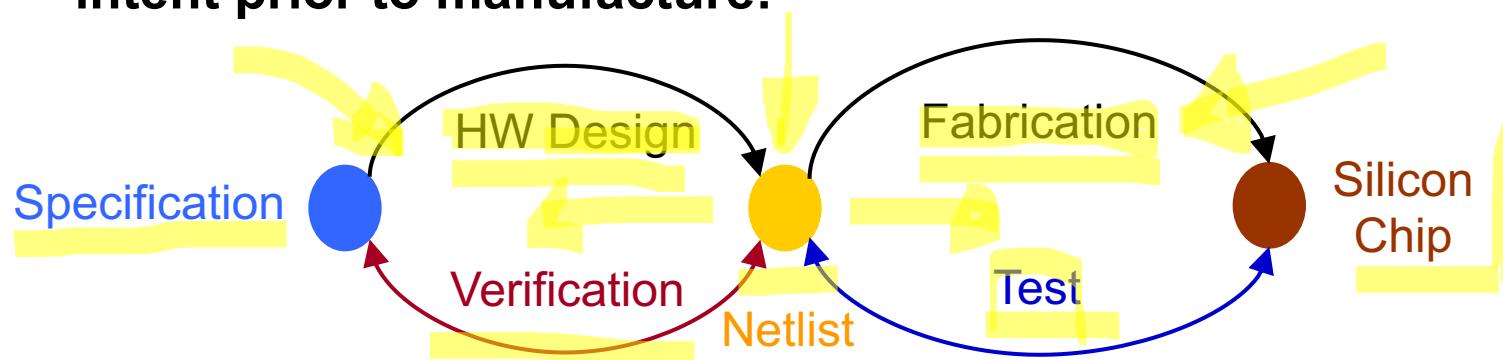

- Purpose of verification is to ensure that the result of some transformation is as intended or as expected.

Verification vs. Test

- Often confused in the context of HW design!
 - Purpose of test is to show design was **manufactured** properly.
 - **Verification** is done to ensure that **design meets its functional intent prior to manufacture!**

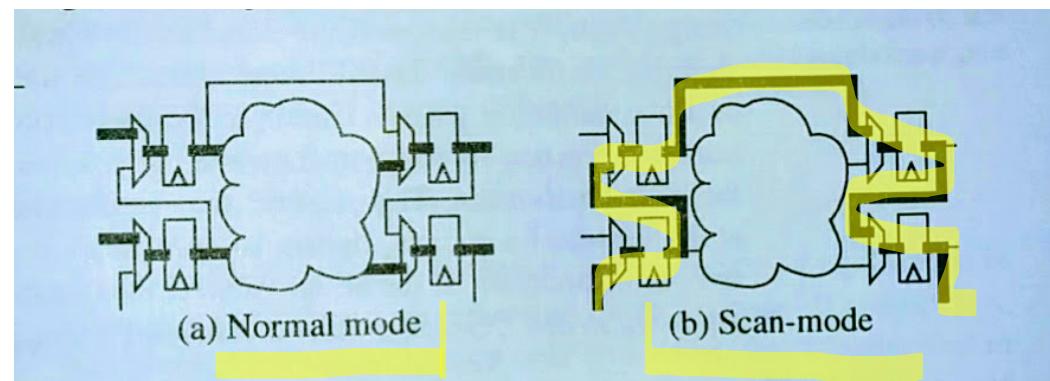

Design for Test

- One method employed during the test phase to facilitate testing is scanning
 - Link all internal registers together into a chain.
 - Chain accessible from chip pins.
 - Allows control/observation of internal state.
 - Impacts area of design, but keeps testing cost down.

Figure from the book "Writing Testbenches" by J. Bergeron

- This is a "**Design for Test**" methodology

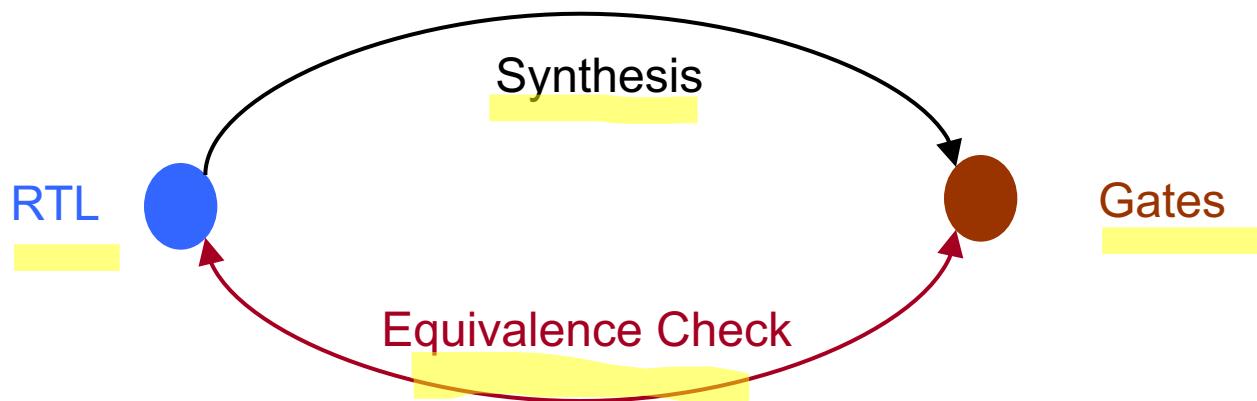

- Why not "**Design for Verification**"? [Hot topic of research!]
 - @ design time, consider: What is design supposed to do? How will it be verified?

Formal: Equivalence Checking

Compares two models to check for equivalence.

- Proves mathematically that both are *logically equivalent*.
 - Commonly used on **lower levels** of design process.
- Example: RTL to Gates (Post Synthesis)

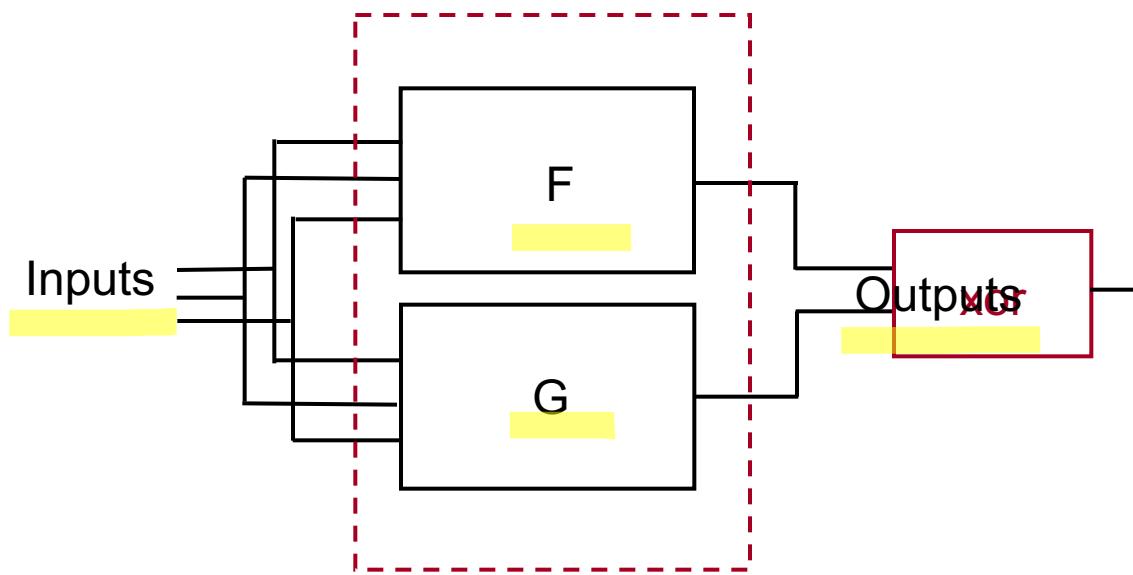

Why do equivalence checking when EDA tools exist for synthesis?

- See "HDL Chip Design - A Practical Guide for Designing, Synthesising, and Simulating ASICs and FPGAs using VHDL or Verilog" book by Douglas Smith page 136 and compare MUX spec with what they claim will be synthesised!

Equivalence Checking

- Conceptually, we are asking the question:
*“Is there an input vector such that
the output of the XOR gate can be 1”?*

Cost of Verification

Necessary Evil

- Always takes too long and costs too much.
- As number of bugs found decreases, cost and time of finding remaining ones increases.

So when is verification done?

(Will investigate this later!)

- Remember: Verification does not generate revenue!

Yet indispensable

- To create revenue, design must be functionally correct and provide benefits to customer.
- Proper functional verification demonstrates **trustworthiness** of the design.
- Right-first-time designs demonstrate **professionalism** and "increase" reputation of design team.

Verification is similar to statistical hypothesis testing

Hypothesis "under test" is: **The design is functionally correct, i.e. there are no bugs in the design.**

		Good Design (no bugs in design)	Bad Design (buggy design)
		Bugs found	
Bugs found	No Bugs found		

Verification is similar to statistical hypothesis testing

Hypothesis "under test" is: **The design is functionally correct, i.e. there are no bugs in the design.**

		Good Design (no bugs in design)	Bad Design (buggy design)
Bugs found	Bugs found	Type I: False Positive	
	No Bugs found		

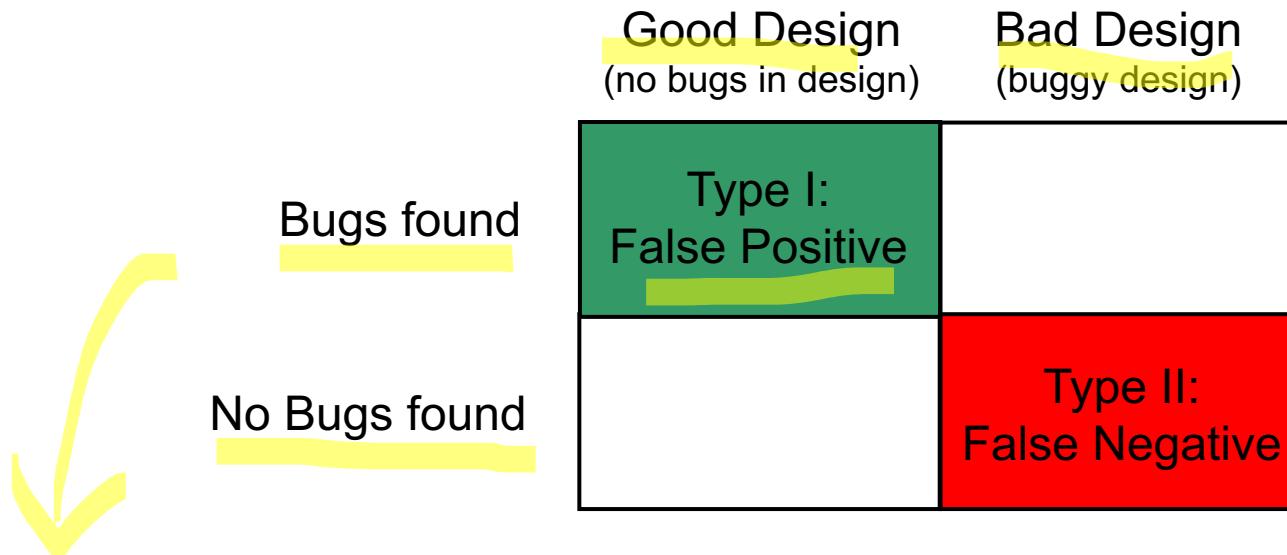

Type I mistakes (“convicting the innocent”, a “false alarm”):

- Easy to identify - found error where none exists.

Verification is similar to statistical hypothesis testing

Hypothesis "under test" is: **The design is functionally correct, i.e. there are no bugs in the design.**

Type I mistakes ("convicting the innocent", a "false alarm"):

- Easy to identify - found error where none exists.

Type II mistakes ("letting the criminal walk free", a "miss"):

- Most serious - verification failed to identify an error!
- Can result in a bad design being shipped unknowingly!

Summary

- **What is Design Verification?**
 - Why do we care?
 - Verification vs validation
- **Bugs**
 - Sources of bugs
 - Cost of bugs
 - Importance of Design Verification
- **Impact of increasing design complexity**
 - ITRS
 - Shrinking time to market windows
 - Increasing Productivity
- **The chip design process**
 - Where does Verification “fit”?
- **Reconvergence Models**
 - Help us identify what is being verified

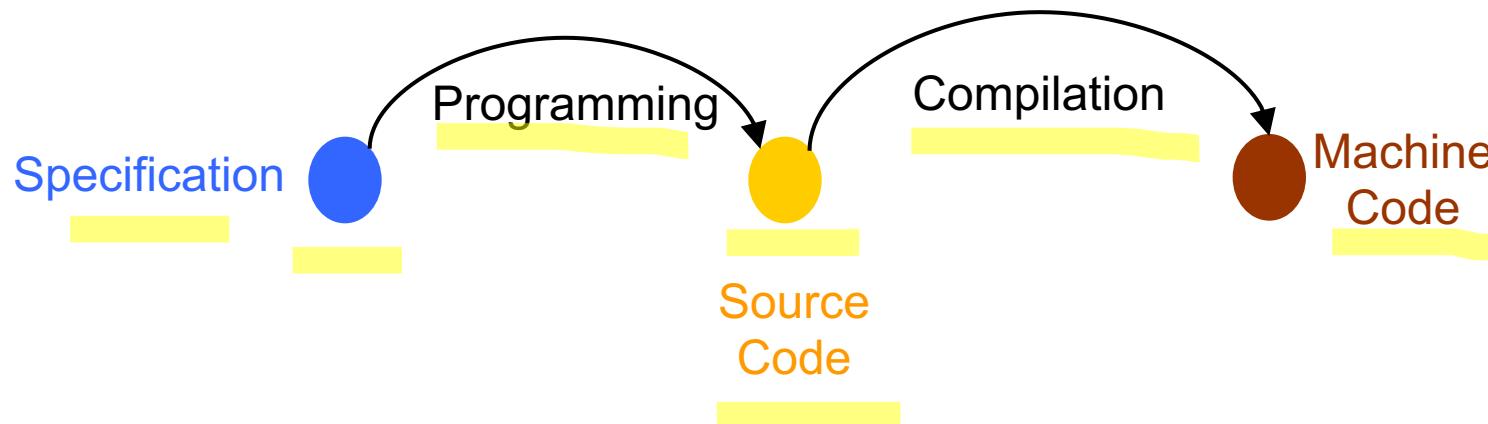

Reconvergence models are the starting point for any verification activity!

When asked to verify something, first draw a reconvergence model and see whether you've got all you need to perform verification!

Reconvergence Models – another example

- In SW development, the transformative process from specification to source code is “programming”.
- The compiler then translates source code to machine code.

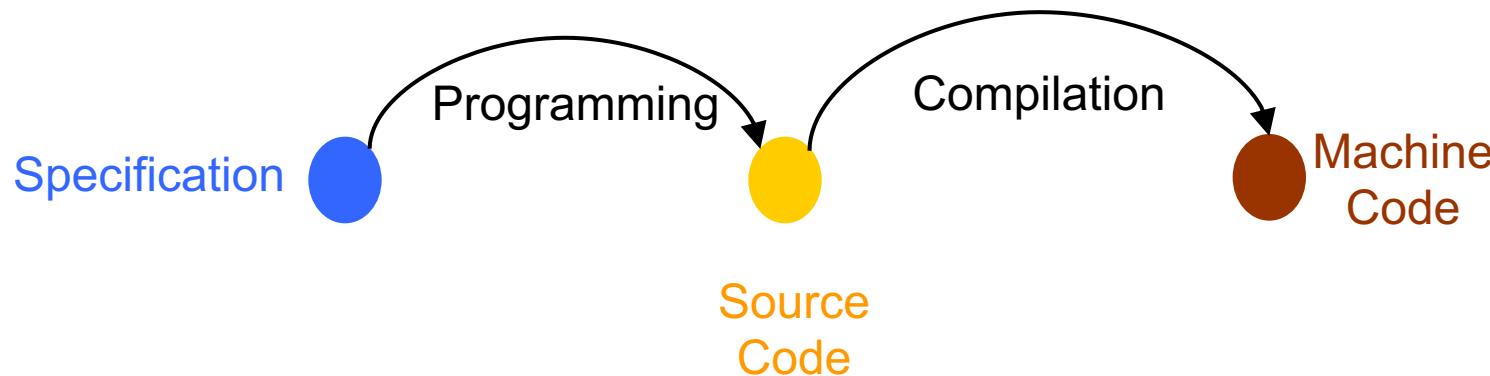

This slide is intentionally
left blank for you to take
some time to attempt the
task on the
reconvergence model on
programming ☺

Please do not proceed until you've tried
– you'll learn more if you try.

Reconvergence Models – another example

- In SW development, the transformative process from specification to source code is “programming”.
- The compiler then translates source code to machine code.

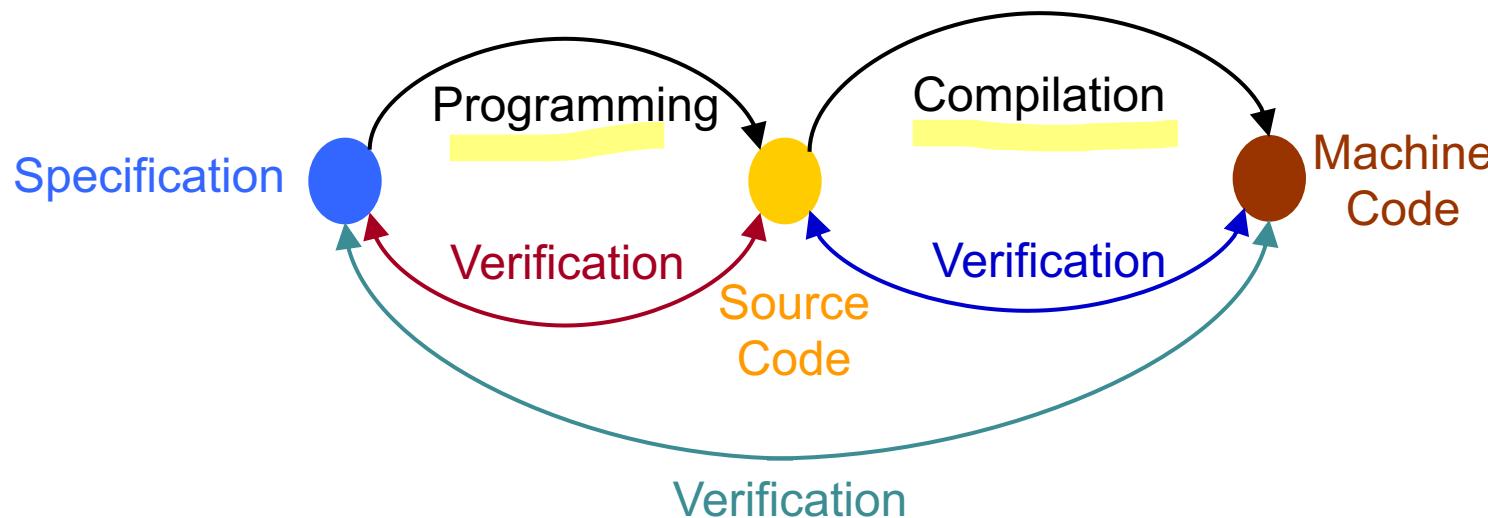

- If your program does not work, why could this be?
 - Bugs in the programming
 - Bugs in the compiler
 - Misunderstanding of the specification
 - <What else?>
